SECTION 1

1.0 INTRODUCTION

1.1 Authorization

NUS Corporation performed this work under Environmental Protection Agency Contract No. 68-01-6699. This specific report was prepared in accordance with Technical Directive Document No. F3-8403-07 for the Rhinehart Tire Dump located in Frederick County, Winchester, Virginia.

1.2 Scope of Work

NUS Corporation was tasked to complete a desk-top Preliminary Assessment, Site Inspection, and Hazard Ranking report for the subject project, based upon sample analyses data and other information provided by the U.S. EPA and the Virginia State Water Control Board (VA SWCB). The Hazard Ranking report has been submitted under separate cover.

1.3 Summary

After reviewing data and reports supplied by EPA and the VA SWCB, as well as discussing the site with Virginia officials, NUS FIT III completed a desk-top Preliminary Assessment and Site Inspection report.

The Rhinehart Tire Dump is approximately 5 acres and is located in a ravine on private property adjacent to an unnamed tributary to Hogue Run. In 1972, Mr. Paul Rhinehart, the site owner, began a tire disposal operation which consisted of transporting rubber tires from various locations to the ravine for ultimate disposal.

On October 31, 1983, the tire dump caught fire. Although the fire was brought under control within a short period, the dump continued to smolder for several months. The exact date at which the fire was declared entirely extinguished is unavailable. Combustion processes resulted in the contamination of air and the by products of the fire contaminated surface water and groundwater within the site vicinity.

Several containment basins were constructed in an effort to mitigate surface water contamination. In addition to the containment basins, several groundwater monitoring wells were also constructed in and around the disposal area. Sampling from the test wells and residential supply wells has shown contamination in the test wells only. On February 13, 1984, the site owner consented to a C.E.R.C.L.A. Section 106 Order issued by EPA requiring control of on-site drainage.

SECTION 2

2.0 THE SITE

2.1 Location

The Rhinehart Tire Dump is located in Western Frederick County, Virginia, in a sparsely populated area approximately 3/4 miles northwest of the town of Mount Pleasant. The nearest major road in the area is County Road 608, which passes through the town of Mount Pleasant. The town of Winchester is approximately 6 miles east of the site.

2.2 Site Layout

The site consists of a ravine which was filled with waste rubber tires. Although a fire at the site in 1983 reduced the volume of materials in the ravine, the original area of fill was estimated at 600 feet long by 375 feet wide with depths ranging from 20 to 40 feet.

An unnamed tributary to Hogue Run is located approximately 100 feet north of the site. Topography is such that drainage from the ravine area flows toward this stream. The general area slopes 20 to 35 percent in a north westerly direction and elevations range from 920 feet to 1,000 feet mean sea level (MSL).

Following the 1983 fire at the subject site, EPA authorized the construction of several containment structures down slope from the ravine. Currently, there are 3 of these structures on the site. The primary containment lagoon, an unlined 50,000 gallon capacity pond, is located immediately down slope from the burn area. The second lagoon, a lined 400,000 gallon capacity pond, is located adjacent to the primary lagoon. The third containment lagoon, its capacity is estimated at 1/4 of that of the second lagoon, is located adjacent to the unnamed tributary. This lagoon functions as a safety valve to ensure that oils from the second lagoon do not enter the unnamed tributary.

2.3 Ownership History

Previous owners of the property are not known. Mr. Paul Rhinehart has owned the property for at least the past 12 years.

2.4 Site Use History

Although records are not available, the Frederick County Administration reports that the site had been used to raise horses in the past. In 1972, Mr. Rhinehart began accepting old tires for disposal on his property. Mr. Rhinehart owns several trucks that had delivered discarded tires to the site from locations up to 200 miles away. In addition to operating this business, Mr. Rhinehart had built an incinerator that was to be used to test a process that would recover carbon black and oils from the discarded tires. The incinerator was never put into operation.

2.5 Permit and Regulatory Action History

As of the this time, there have been no permit or regulatory actions associated with the subject site. However, due to complaints by local residents, activities on site were halted persuant to a circuit court action.

2.6 Remedial Action To Date

With the exception of the construction of containment structures to prevent the discharge of oils from entering adjacent surface waters and the removal of by-product oils from containment structures at the site, there have been no remedial actions to remove or properly dispose of the materials remaining on site. Approximately 800,000 gallons of oils produced by the fire have been removed from the containment structures and it is understood that they will be used as blending agents in fuel oils. It has been estimated that approximately 20 percent of the volume of materials originally placed on site remained as of April 2, 1984. On February 13, 1984, the site owner consented to a C.E.R.C.L.A. Section 106 Order issued by EPA requiring control of on-site drainage.

SECTION 3

3.0 ENVIRONMENTAL SETTING

3.1 Surface Waters

The site is drained by a small unnamed tributary along its western edge. This stream joins another unnamed tributary which drains a facing valley. The 2 streams confluence to form Massy Run. Massy Run flows about 1/2 mile west to Hogue Creek. Massy Run is not labeled on the U.S.G.S. Topographic 7.5' quadrangle shown in figure 1 of appendix B. The nearest public water supply intake on Hogue Creek is 22 miles downstream. Most of the on-site activities performed by EPA Emergency Response Team (ERT) were directed toward preventing oily discharges from the fire from entering Massy Run and contaminating Hogue Creek.

3.2 Geology and Soils

The majority of geologic information for this site was obtained from Mr. Thomas Stone, Hydrogeologist for IT Corporation (ERT consultant). The Rhinehart Tire Dump is located on the west side of Hunting Mountain in the Appalachian section of the Ridge and Valley Province. The site is underlain by the Chemung Formation, which is defined on the Virginia Division of Mineral Resources map (by James L. Calver) as consisting of chiefly gray shale and sandstone with thin conglomerates and a few red zones (appendix D). According to Mr. Stone, the monitoring well drill logs for the site show a highly cemented, very hard, mostly fine grained sandstone with some shale and some weathered zones composed of 0.5 to 2.0 inches of clay. The formation is very massive in this area and supports near vertical fractures with a northwest-southeast trend. This alignment concides with the strike of the beds and the strike of Hunting Mountain ridge top to the immediate east of the site. The dip of the beds range from 35 to 50 degrees to the east-southeast.

As shown on the geologic map and cross section (see appendix D), the site is located on the western side of Hunting Mountain. Hunting Mountain is entirely within the Chemung Formation and is on the western limb of the Pleasant Mountain Syncline, which plunges to the south. Within a few thousand feet, east of the site, is the overlying Hampshire Formation which is comprised of red shale, mudrock, and sandstone. To the west is the underlying Braillier Formation which consists of greenish to brown micaceous shale with thin intercalated layers of fine-grained gray sandstone. Mr. Stone estimates that the actual thickness of the Chemung Formation in the site area is approximately 1,500 feet; however, since the beds are dipping, the apparent (vertical) thickness of the formation is roughly 2,000 feet. The entire thickness of the Chemung Formation is exposed at the surface with the site situated in the mid to lower strata.

The overburden in the immediate site area ranges in thickness from 20 to 30 feet on the average, but can be completely missing in the stream valleys as is the case along Massy Run. In general, the overburden is thickest on the side slopes of Hunting Mountain and thins toward the valley. The overburden is composed of weathered Chemung and, as such, consists of sandstones, shales, and clays. The sequence is gradational to bedrock with alternating layers of relatively competent material. The extent to which Mr. Rhinehart reworked the soils in the site area has not been determined. According to Mark Davis (Frederick County District Conservationist), the soils in the site area were mapped as belonging to the Wiekurt Berkes Channery silt loam 25 to 65 percent series.

3.3 Groundwaters

Information on groundwater in the vicinity of the site was obtained from a telephone conversation with Mr. Stone. IT Corporation installed 7 monitoring wells at the site and is in the process of finalizing a hydrogeologic assessment. According to Mr. Stone, there is no definable aquifer under the site. This is due to the presence of near vertical joints and steeply dipping beds which intersect the overburden allowing surface water to be communicated into the bedrock readily. However, there are essentially 2 flow regimes within the site area. The upper regime mainly occupies the overburden and mimics topography at an average depth of 10 feet. Flow in the overburden is generally toward the unnamed tributary and Massy Run. Deep flow in the bedrock follows a more regional path believed to be in a southeastern direction toward the axis of the synclines in the direction of plunge. Mr. Stone stated that the near surface flow is complicated by a positive vertical flow component (artesian) which impedes the infiltration of surface waters into the ground. As a result, most contaminants probably flow to the nearest downgradient stream. Some lateral flow has been observed in the overburden. Latteral flow is produced by the combined effects of the positive vertical flow component, the presence of alternating layers of relatively competent and highly weathered material in the overburden, and near vertical joints and fractures. Hydraulic conductivity rates, as determined by Mr. Stone, were 5.4×10^{-6} feet/sec. (1.6×10^{-4} cm/sec) for the overburden and 1.4×10^{-4} ft./sec (4.2×10^{-3} cm/sec) for the bedrock as noted in appendix E. Flow in the bedrock ranged from 0.1 gpm to 15 gpm and intersected. Reduced flow in the overburden is due to the presence of weathered material which collapses and clogs the secondary porosity near the surface.

Three (3) of the monitoring wells were installed into bedrock and 4 were installed into overburden. The maximum range in elevation monitored by the wells is 168 feet from the base of the highest well to the base of the lowest well. Little correlation can be drawn from this, which will be discussed in IT Corporation's final report. The range or extent of contamination has not been completely determined. The state of Virginia conducted a survey of the homes in the area; the results of contamination found in these wells, in conjunction with the geology, will be presented in IT Corporation's report.

According to Mr. Stone, Mr. Rhinehart draws his drinking water from an artesian spring above the site. Analysis of his water has shown no contamination to date. The next closest residential well is approximately 1/4 mile away, according to Mr. Stone. Mr. Stone stated that local drillers told him that people on Hunting Mountain ridge have wells drilled to 300 feet or more. Mr. Stone does not know of any contamination in these bedrock wells. He said that some wastes have entered the bedrock on site, but that these wastes will probably leave through the streams. Contamination is not expected to move downward to much extent.

3.4 Climate and Meteorology

The climate of the Frederick County area is characteristic of a humid continental-type marked by extreme seasonal temperature changes. The mean annual air temperature is about 53°F. Annual precipitation is about 38 inches. The distribution of rainfall, which is nearly uniform throughout the year, reaches a maximum in August. The climate is modified by the higher humidity of the Atlantic Coastal area.

3.5 Land Use

The land usage in the site vicinity is largely rural. There are, however, some agricultural and pasture lands as well as a few small residential villages within a 3-mile radius of the site.

3.6 Population Distribution

There are approximately 20 homes or about 76 people residing within a 1-mile radius of the site. Most of these homes are located approximately 3/4 of a mile southeast of the site in the village of Mount Pleasant. Based on a U.S.G.S. topographic map house count, an estimated 40 residences, or 152 persons, are located within a 3-mile radius of the site.

3.7 Water Supply

Water supplies in the area of the site, which draw water from the aquifer of concern (Chemung Formation), are provided by private domestic wells. There are no other sources of drinking water currently available. Local residential wells and test wells have been sampled. Although the test wells have shown contamination, no domestic wells have been found to be contaminated (see appendix C).

3.8 Critical Environments

Hogue Creek is a state designated "put and take" trout stream.

SECTION 4

4.0 WASTE TYPES AND QUANTITIES

Records of the materials deposited on site prior to the fire were not kept or required, since there were no permits issued to the site. The tires, as deposited on site, were not considered hazardous materials. An unknown quantity of hazardous substances, including benzene, phenol, chloroform, and styrene were released to the air as a result of the fire. An unknown quantity of hazardous materials, including benzene, phenol, methylene chloride and toluene, have been released to surface and groundwaters adjacent to the site as byproducts of the fire. These oils were partially contained within the previously described lagoons and eventually removed from the site.

07 COMMENTS
The site was used for storage of old tires. The tires were simply piled on the ground. No permits exist for the site because the old tires were placed on private property and were not considered to be of a hazardous nature. No precautions were taken by the owner to contain the tires or to prevent access to the site.

IV. CONTAINMENT

01 CONTAINMENT OF WASTES (Check one)

☐ A. ADEQUATE, SECURE ☐ B. MODERATE ☒ C. INADEQUATE, POOR ☐ D. INSECURE, UNSOUND, DANGEROUS

02 DESCRIPTION OF DRUMS, DIKING, LINERS, BARRIERS, ETC.
Surface impoundments were constructed by EPA after the fire was started in an effort to contain waste oils produced due to the fire on site. Three containment impoundments were constructed. Primary containment was an unlined lagoon with a 50,000 gallon capacity. Secondary containment was a lined lagoon with a capacity of approximately 400,000 gallons. The third lagoon was a back up to the secondary impoundment and was not used.

V. ACCESSIBILITY

01 WASTE EASILY ACCESSIBLE: ☒ YES ☐ NO

02 COMMENTS
Old tires were placed in a ravine on site. No barriers or other precautions exist.

VI. SOURCES OF INFORMATION (Cite specific references, e.g. state files, sample analysis, reports)

14 DESCRIPTION OF SITE IN RELATION TO SURROUNDING TOPOGRAPHY

The site is located near the summit of Hunting Ridge in the ridge and valley province of the Blue Ridge Mountains. As a result, the surrounding topography consists of wooded hills and valleys with rather steep grades.

POTENTIAL HAZARDOUS WASTE SITE
IDENTIFICATION AND PRELIMINARY ASSESSMENT

REGION	SITE NUMBER (to be assigned by Hq)
III	VA-278

NOTE: This form is completed for each potential hazardous waste site to help set priorities for site inspection. The information submitted on this form is based on available records and may be updated on subsequent forms as a result of additional inquiries and on-site inspections.

GENERAL INSTRUCTIONS: Complete Sections I and III through X as completely as possible before Section II *(Preliminary Assessment)*. File this form in the Regional Hazardous Waste Log File and submit a copy to: U.S. Environmental Protection Agency; Site Tracking System; Hazardous Waste Enforcement Task Force *(EN-335)*; 401 M St., SW; Washington, DC 20460.

I. SITE IDENTIFICATION

A. SITE NAME: Rhinehart Tire Dump

B. STREET *(or other identifier)*: Mt. Falls

C. CITY: Winchester

D. STATE: VA

E. ZIP CODE: 22601

F. COUNTY NAME: Frederick

G. OWNER/OPERATOR *(if known)*

1. NAME: Mr. Paul Rhinehart
2. TELEPHONE NUMBER: unknown

H. TYPE OF OWNERSHIP

☐ 1. FEDERAL ☐ 2. STATE ☐ 3. COUNTY ☐ 4. MUNICIPAL ☒ 5. PRIVATE ☐ 6. UNKNOWN

I. SITE DESCRIPTION

Approximately 5 acre site in a ravine which is used for storage of discarded tires. The site is adjacent to an unnamed tributary of Hogue Creek.

J. HOW IDENTIFIED *(i.e., citizen's complaints, OSHA citations, etc.)*: Ms. Eve Thorsen - Virginia Emergency Services

K. DATE IDENTIFIED *(mo., day, & yr.)*: 10/31/83

L. PRINCIPAL STATE CONTACT

1. NAME: Mr. Ray Tesh - Virginia State Water Control Board - Director - Division of Surveillance and Field Studies
2. TELEPHONE NUMBER: (703) 828-2595

II. PRELIMINARY ASSESSMENT *(complete this section last)*

A. APPARENT SERIOUSNESS OF PROBLEM

☒ 1. HIGH ☐ 2. MEDIUM ☐ 3. LOW ☐ 4. NONE ☐ 5. UNKNOWN

B. RECOMMENDATION

☐ 1. NO ACTION NEEDED *(no hazard)*

☐ 2. IMMEDIATE SITE INSPECTION NEEDED
a. TENTATIVELY SCHEDULED FOR:
b. WILL BE PERFORMED BY:

☐ 3. SITE INSPECTION NEEDED
a. TENTATIVELY SCHEDULED FOR:
b. WILL BE PERFORMED BY:

☒ 4. SITE INSPECTION NEEDED *(low priority)*
Groundwater and surface water is and should be monitored periodically.

C. PREPARER INFORMATION

1. NAME: David R. Kindig, NUS FIT III
2. TELEPHONE NUMBER: (215) 687-9510
3. DATE *(mo., day, & yr.)*: 3/26/84

III. SITE INFORMATION

A. SITE STATUS

☐ 1. ACTIVE *(Those industrial or municipal sites which are being used for waste treatment, storage, or disposal on a continuing basis, even if infrequently.)*

☒ 2. INACTIVE *(Those sites which no longer receive wastes.)*

☐ 3. OTHER *(specify)*: _____ *(Those sites that include such incidents like "midnight dumping" where no regular or continuing use of the site for waste disposal has occurred.)*

B. IS GENERATOR ON SITE?

☒ 1. NO ☐ 2. YES *(specify generator's four-digit SIC Code)*:

C. AREA OF SITE *(in acres)*: approximately 5

D. IF APPARENT SERIOUSNESS OF SITE IS HIGH, SPECIFY COORDINATES

1. LATITUDE *(deg.-min.-sec.)*: 39° 10' 50"
2. LONGITUDE *(deg.-min.-sec.)*: 78° 18' 10"

E. ARE THERE BUILDINGS ON THE SITE?

☐ 1. NO ☒ 2. YES *(specify)*: a small shed is located adjacent to the site.

Dear Mr. Ostrauskos:

Attached are copies of lab data on water samples taken at the Tire Fire site in Frederick County. The data was performed by the State. Lab. Please note that the date which the lab received the samples is the next day following the sampling.

These are all of the data which I have. As more is received, a copy will be forwarded.

Very truly yours,

Date Received: 11-04-83

Identification No.:

Lab #: 10583-10587

Submitted By: Dave Chance

Analyst: James C. Peterson, Ph.D.

Description:

10583--Unnamed tributary to Hogue Creek
Upper portion unnamed tributary--pool of collected product

10584--Unnamed tributary to Hogue Creek
Free flowing stream upper portion, just above big pool of product

10585--X-tributary Hogue Creek
Lower portion unnamed tributary from fire site

10586--Hogue Creek Control
Hogue Creek just above confluence with unnamed tributary from fire site

10587--Hogue Creek
Hogue Creek downstream from confluence with unnamed tributary from fire site

Results:

Priority Pollutants	10584	10585	10586	10587
Benzene	0.9ug/L	1.3ug/L	0.3ug/L	0.5ug/L
Toluene	1.7ug/L	2.3ug/L	<0.2ug/L	<0.2ug/L
Ethylbenzene	4.6ug/L	1.2ug/L	0.8ug/L	<0.2ug/L
Xylenes	2.4ug/L	0.6ug/L	<0.2ug/L	<0.2ug/L
Naphthalene	30 ug/L	10 ug/L	<1 ug/L	<1 ug/L
Fluorene	13 ug/L	4.6ug/L	<1 ug/L	<1 ug/L
Phenanthrene	4.1ug/L	2.0ug/L	<1 ug/L	<1 ug/L
Caprolactam	13 mg/L	4.8mg/L	140 ug/L	210 ug/L

Other Components Identified in 10584, 10585, 10586, 10587:
Benzonitrile, Acetophenone, Tolunitrile, Phthalonitrile, Benzothiazole, Methyl benzothiazole, 1-methyl naphthalene, C_3 benzenes, C_4 benzenes

Sample 10583 was redundant with 10584 and was not analyzed.

Dear Mr. Ostrauskos:

Attached are copies of lab data on water samples taken at the Tire Fire site in Frederick County. The data was performed by the State Lab. Please note that the date which the lab received the samples is the next day following the sampling.

These are all of the data which I have received since I last corresponded on 13 February 1984. As more is received, a copy will be forwarded to update your file.

Very truly yours,

R. F. Tesh, Director

FREDERICK COUNTY, VIRGINIA TIRE FIRE

Technological Considerations and Approach Regarding the Fire

Background

In November, 1983 ERT developed a report entitled "Determination of Long Term Superfund Immediate Removal approaches for Frederick County Tire Fire". This report identified several possible options for dealing with the fire under the following three major categories:

I. Controlled Burning, Containment and Collection of Pyrolytic Tar (Status Quo)

II. Accelerated Burning of the Pile

III. Extinguish the Fire

On November 21, 1983, IT Enviroscience was tasked to do a feasibility study and cost estimate on the most viable options in each category. The resulting IT Report entitled "Report on Recommendation for the Frederick County Tire Fire" was made available to EPA Region III and the State on December 8, 1983, and is the basis for our current operating mode on scene. On December 9, 1983 EPA Region III held a meeting on scene with the State and various technical experts to discuss the findings of the report.

Findings of IT Report

I. Extinguish the fire - three options considered

A. Injection of gas such as Nitrogen or Carbon Dioxide to break the flow of air into the tire fire.

Rejected because:

1. distribution system needed to inject gases too uncertain
2. cost of gas prohibitive ($4 million minimum)
3. it could take up to 400 days to cool the pile, during which time the oil could continue to flow
4. volume of gas needed (2.3×10^9 scf)

B. Injection of steam (water) to cool tires to a temperature below the reignition point.

Rejected because:

1. actual test of this option proved unsuccessful

ORIGINAL
(Red)

C. Smother fire by covering it with dirt - this is the option recommended in IT's report - approximate cost $375,000.00

Temporarily rejected because:

1. property owner's consent would be required
2. EPA would be creating a landfill and possible leachate problems
3. cool down period may still be 400 days during which time the oil could continue to flow (the main problem at the site would still not be solved)
4. the oil flow from the site has steadily been decreasing (presently 1-4 gpm) and may stop in another month, making it unnecessary to extinguish the fire
5. covering the fire may prove too dangerous.

II. Accelerate Burning -

A. Injection of air into the pile to accelerate burning

Rejected because:

1. there would be a higher rate and quantity of air emissions
2. an extremely large air flow rate (200,000 - 400,000 scfm) would be needed to significantly reduce the burn rate. This would require a complex and expensive distribution system.

III. Status Quo -

A. Allow fire to burn, continue to contain and collect the tar

this is the option currently being practiced by the region because:

1. no environmental monitoring data collected so far indicates an immediate need to extinguish the fire
2. all of the options considered so far for extinguishing the fire have undesirable elements associated with them that argue in favor of maintaining status quo approach
3. the oil flow is decreasing to the point that it may stop shortly, or to the point that the oil can be dammed up in the fire - in which case the removal action will be over
4. the present collection system has successfully dealt with the principal contamination problem associated with this fire. Industry experts have recommended that the oil collection, not the fire be the main concern of the Agency.

In light of the options presented above, it is the Region's opinion that EPA should maintain status quo efforts for at least another month or two before making any decision on dealing with the fire. During this time, response costs will be scaled down to a "bare bones" operation, and other options for extinguishing the fire, which are outside the scope of the IT report, can be considered.

ORIGINAL

CHRONOLOGY of FUNDING REQUESTS and EXPLANATION of NEED

11/02/83 Regional Administrator approves $250,000.00 (limit of his funding authority) to initiate action.

11/04/83 On-Scene Coordinator (OSC) requests $500,000.00 ceiling increase but is granted only $225,000.00 by Headquarters that same day.

11/08/83 OSC requests $425,000.00 ceiling increase bringing project ceiling to $900,000.00 - NOTE: According to Removal Guidance OSC could not request an increase that would cause project ceiling to exceed $900,000.00 prior to requesting an exemption of the $1 million limitation on removals.

11/09/83 Ceiling increase granted by Headquarters.

11/14/83 Exemption to $1 million limitation requested.

11/17/83 Exemption granted - OSC is now free to request another ceiling increase.

11/17/83 OSC requests ceiling increase of $250,000.00 to deal with unanticipated wash out of containment structures due to heavy rains.

11/18/83 Ceiling increase granted.

11/21 - 12/09/83 Period of time during which ERT and IT are developing a report on the feasibility of putting ou the fire.

11/29/83 OSC requests ceiling increase of $200,000.00 in order to maintain site operations while awaiting completion of IT report. Recommendations of report will determine future course of action and cost.

12/01/83 Ceiling increase granted.

12/09/83 Report issued - EPA and State decide not to attempt to extinguish fire but to continue collection operation and enter into a planned removal.

12/20/83 OSC requests ceiling increase of $100,000.00 in order to carry on site operations while developing planned removal.

12/21/83 Headquarters approves only $35,000.00 increase.

EXPLANATION

MISSISSIPPIAN

Mpg

Pocono (?) formation

Shale, sandstone, and conglomerate. Noted only in Shockeys Knob along the Virginia - West Virginia boundary.

DEVONIAN

Dhs

Hampshire formation

Chiefly red shale, mudrock, and sandstone.

Dch

Chemung formation

Chiefly gray shale and sandstone with thin conglomerates and a few red zones.

Db

Brallier formation

Greenish to brown micaceous shale with thin intercalated layers of fine-grained gray sandstone.

Dha

Hamilton formation

Dark-gray to olive-green fine-grained sandstone with interbedded dark-colored shale.

Dm

Marcellus shale

Dark-gray to black, fissile shale; weathers gray.

Don

Onondaga formation

Dark-green, non-fissile shale; in part calcareous.

Oriskany sandstone

Gray to white, coarse-grained, thick-bedded sandstone.

New Scotland limestone

ORDOVICIAN

O

Juniata form

Chiefly red shale or red, and thin-bedded, red, ark

Oswego form

Gray and greenish, thi grained sandstone and co

Omb

Martinsburg f

Brownish, fissile shale nated, fine-grained sands

Oe

Edinburg (Chamber formatic

Dark-gray to black, comp nodular layers, thin sills amounts of black shale.

Ol

Lincolnshire (Lenoi

Dark-gray, finely crystall stringers and nodules of b

New Market (Moshe

Dove-colored, compact, t stone.

Obe

Bellefonte (Upper B formatio

Light to dark-colored lim crystalline gray dolomite.

Nittany Lower Bee formation

Bluish-gray li stone wit of gray dolom

AND: DAVID R. KINDIG (NUS)

DISCUSSION:

Groundwater monitoring/testing has distinguished 2 levels of groundwater (shallow and deep).
- shallow flow is to NW, deep flow has not been defined
- groundwater in shallow aquifer shows a 100 ft gradient over ~1 mile to NW
- contamination is confined to shallow aquifer with a majority surfacing at the unnamed tributary to Hague Creek - no long range contamination problem, should have decreasing concentrations over the years
- unsat. zone - permeability (hyd. conductivity) = 10^{-6} ft/sec, and 10^{-4}-10^{-5} ft/sec in bedrock
- home wells are in deeper aquifer and are unaffected (200-300' deep)

RE: Confirmation of geology/hydro. information collected by IT consultant at Rhinehart Tire Fire.

BETWEEN:	OF:	PHONE:
Tim Stone - Hydrogeologist	IT Corp	(201) 548-9660

AND:

Martin R. Howe - Geologist / Hydrogeologist (NUS)

DISCUSSION:

- Underlying formation is the Chemung. Strike NE-SW, Dip 45° ESE, syncline plunges southerly in area of site. ≈1500 ft thick ≈2000 ft vertical thickness to underlying formation
- Bedrock was mostly fine grained, very hard, sandstone, some shale, some ~~the~~ weathered zones / ½" to 2" clay zones. Some fracture traces. Most of the formation was very massive.
- Thickness of the overburden ranged from 0-30' in and around the site and averaged about 20-30 feet. Generally, thickest near top of ridge and absent in valley (stripped off by stream). Massy Run ~~runs~~ is into bedrock.
- The overburden is gradational to bedrock with definite zones of competence.
- Flow believed to be mostly confined to the overburden in this area & ultimately discharges to Massy Run. Artesian conditions in the bedrock created by topographic relief off Hunting Ridge produce a vertical flow component believed to be strong enough to ~~impede~~ impede most flow infiltration. Infiltration from surface to bedrock would be greatest in areas of thin or ~~no~~ existing ~~bedrock~~ overburden. Shallow well

ACTION ITEMS:

pot in Massy Run showed some contamination. This was expected because it is believed that Rhinehart's pond has discharged to the run in the past. The only bedrock well to show contamination was a well ~~placed~~ installed directly downgradient of the fire pile.

- Since only 3 bedrock wells were installed, IT Corp. could not accurately determine regional flow direction for the area. It is suspected the regional flow would be in a ~~south~~ east direction ~~to~~ towards

BETWEEN:	OF:	PHONE:
Tim Stone - Hydrogeologist	IT Corp.	(701) 548-9660

AND:

M. Howe (NUS)

DISCUSSION:

the structural nature of the geology in the site area. Principal flow is believed to along near vertical joint sets. Fracture traces measurments reveal a SE-NW alignment of the joints. These vertical joints allow artesian flow to force water in the overburden up thus impeding infiltration.

A leachate (oily) seep was found abt. 50 to 75 feet laterally of the pond area. Trenching revealed that flow was along a more competent zone within the overburden.

Mr. Stone believes that it is possible for wastes from the site to enter the bedrock aquifer however it would most likely travel toward and ultimately discharge to Wilson Run. Infiltration seems to depend on the thickness of the overburden and to what degree it has been reworked. It is not known to what extent Mr. Rhinehart reworked the soils in the site area prior to starting the dump.

ACTION ITEMS:

There are over a dozen home wells in the area. Drillers for IT Corp stated to Mr. Stone that Wells near the ridge top (Hunting Ridge) go to a depth of 300'. Yields in the bedrock are between .1 to 15gpm which seems to depend on the amount of fractures hit. Mr. Rhinehart draws water from a spring on his property. Analysis of this spring has yet to show contamination. Rhinehart's well is the closest to the site. Next closest is .45 miles or so away.

REPLY TO ATTN OF: Harry L. ATTen, Ph.D.
Environmental Response Branch

SUBJECT: Transmittal of the Preliminary Environmental Assessment Report for the Rhinehart Tire Fire

TO: Thomas Massey, Senior On-Scene Coordinator
Environmental Protection Agency, Region III

THRU: J. Stephen Dorrler, Chief
Environmental Response Branch

Enclosed is Environmental Response Team's Preliminary Environmental Assessment Report for Rhinehart Tire Fire, Winchester, Virginia.

Since I anticipate questions, complaints, and/or praise for this report, I have included most of the documentation with the names of the preparers as appendices. The principal ERT contacts are Rod Turpin for the air work and myself for the rest of the report. I have not included the ERT Field Data Sheets or the Analytical Reports from ETC, Inc. for the ERT water quality data summarized in Table 5.

If we can be of any additional assistance, please do not hesitate to call.

PRELIMINARY ENVIRONMENTAL ASSESSMENT REPORT

RHINEHART TIRE FIRE
WINCHESTER, VIRGINIA

FEBRUARY 1984

ENVIRONMENTAL RESPONSE TEAM
WOODBRIDGE AVENUE, EDISON, NEW JERSEY

PRELIMINARY ENVIRONMENTAL ASSESSMENT OF THE RHINEHART TIRE FIRE

1.0 BACKGROUND

At about 1:00 A.M. on October 31, 1983, a fire of suspicious origin broke out in a 5-acre tire storage area on a steep hillside on the Rhinehart property near Winchester, Frederick County, Virginia. Fire fighters failed to control the blaze, which spread to engulf an estimated 5 to 7 million tires. Black smoke from the fire was visible over twenty miles away. Shortly after the fire started, hot oil produced from melting and pyrolysis of the tire mass, began to seep out of the toe of the tire pile and into an unnamed tributary to Hogue Creek. An unestimated quantity of oil flowed into Hogue Creek, which is a tributary to the Potomac River system. The nearest public water supply intake on this system is 22 miles downstream.

On October 31st, a catch basin was installed to trap the oil and to provide water for fighting the fire. High rates of oil and water seepage threatened to exceed the basin's storage capacity and the Environmental Protection Agency (EPA), Region III was activated. Shortly thereafter, Mr. Tom Massey, EPA On-Scene Coordinator, activated the Environmental Response Team (ERT).

1.1 PURPOSE

The ERT was requested to evaluate the immediate hazards to public health relating to air emissions from the fire and to the health and safety of response personnel. An air monitoring program was designed for this purpose. The ERT was also requested to conduct a joint study with the Virginia Water Control Board (WCB) to investigate surface water and groundwater contamination. The surface water study was dovetailed into an emergency monitoring program already being conducted by the WCB. The groundwater program, designed mainly to determine whether contamination is reaching the deeper aquifer, was deferred until the imminent hazard could be brought under control, and is now underway.

1.2 DESCRIPTION OF STUDY AREA

The Rhinehart site is located along Hunting Ridge; in the ridge and valley province of the Blue Ridge Mountains. The location has been mapped by the U.S. Geological Survey (see Figure 1, USGS Hayfield, VA quadrangle). The principal drainage of Hunting Ridge is Hogue Creek, which flows northeast along the strike of the Ridge and collects runoff from tributaries and groundwater outcrops from the wooded transverse valleys along its route. Drainage from the Rhinehart site enters one of these unnamed tributaries, which has been nicknamed "Massey Run" for temporary identification purposes. Hogue Creek has been designated a put-and take trout stream (Class V) by the Water Control Board. Very stringent water quality standards apply.

The site is underlain by a consolidated shale formation with some interbedded sandstone. Overburden consists of weathered bedrock. The strike of the formation is from SW-NE (along the strike of the Ridge). The formation dips to the east-southeast (ESE) at an angle of 35° - 50°. Hence, the bedding planes under the site dip into the Ridge at a downward angle such that one foot of run results in about one foot of drop-back under the tire pile. Groundwater flow in the weathered overburden is clearly toward Massey Run, as attested to by the oil-water seepage. Deeper flow probably follows the exposed bedding planes, particularly towards the southwest, although some flow may be occurring down-dip into the rock formation through fractures or loose joints. The groundwater study will address these concerns in more detail.

The air dispersion characteristics common to the eastern ridge and valley provinces apply to this site. The generally prevailing west to northwest winds carry the plume across the ridge tops and into the valleys beyond. Inversion conditions could lead to an excessive buildup of airborne materials in nearby valleys, which when added to the accumulated emissions from the woodstoves of the residents themselves could produce an air pollution condition. The issue is whether intermediate dispersion is adequate to eliminate this possibility for this particular site. The nearby downwind area is sparsely populated, except for the Rhinehart residence, which is less than 1000 feet from the fire perimeter.

2.0 DESCRIPTION OF SURVEY

2.1 AIR

Primary consideration was given to monitoring of vapors and aerosols in the air and smoke because of the dual needs of establishing respiratory protection levels for exposed workers on-site and establishing a possible evacuation perimeter for affected residents. For both these reasons, air monitoring programs were coordinated with the Centers for Disease Control (CDC) to determine the health risk.

In addition to the ERT air monitoring efforts, CDC requested NIOSH to do some additional air monitoring. The status of the NIOSH effort is unknown at this time.

An integrated air monitoring program was designated and implemented on 11/3/83 in accordance with ERT's protocol for uncontrolled hazardous waste sites. This guideline addresses five steps which provide a rapid and cost-effective characterization of air pollution from the site. The five include: 1) Determining Background Conditions; 2) Determining Concentrations On-site; 3) Determining Site (or Impact) Area Concentrations; 4) Identifying Specific Contaminants (if needed); and 5) Identifying Particulate Contaminants (if needed).

The sampling array is shown in Figure 2. Monitoring stations are described in Table 1. The program consisted of one background station, two off-site downwind stations, six on-site stations and off-site grab samples with the Real-Time Aerosol Monitor (RAM). The following is a breakdown of the type of samples:

1. NIOSH P&CAM-168 (Aromatic Amines) 3-stage silica gel tubes = 11 samples.
2. NIOSH P&CAM-127 (Organic Vapor Scan) 150 mg carbon tubes = 5 samples.
   600 mg carbon tubes = 15 samples
3. ERT 2-stage tubes (Organic Vapors) Tenax/Chromosorb 102 collection tubes = 23 samples
4. OVA/Thermal desorption collection tubes = 6 samples
5. Particulate cassettes for analyses of organic/inorganic contaminants = 14 samples

On November 22, 1983, and again on November 30, 1983, the clean-up contractor began programmed spraying of the fire with water from Rhinehart's pond to reduce the pond volume and to protect the integrity of the retaining dam. Quenching the fire in this manner was of great concern because of the possibility of forming noxious products by limiting combustion at the fire surface and releasing them in the steam generated. Another air monitoring program was begun to duplicate the earlier schemes under the spraying conditions and to provide rapid field data for control of the spraying operation in case high levels of particulates or volatile materials indicated any imminent hazard.

See Appendix A for the ERT Air Monitoring Report.

2.2 SURFACE WATER

The major concerns of the surface water studies included the immediate impacts of the spill on the water resource and on the water supplies downstream and the long term impact of residual seepage on the water supply and on the environment.

The State WCB began to monitor the water quality of Massey Run and Hogue Creek on November 3rd, and has continued monitoring on a weekly to bi-weekly schedule since that time. The WCB sampling locations are shown in Figure 3. The results of the State studies from November 3 to December 16, 1983 arrived in the ERT office on January 19, 1984. The WCB data reports are included as Appendix B. The results of the December 19th survey were obtained by phone a few days later. The WCB samples usually were analyzed for priority pollutant volatiles and several were analyzed for acid compounds, base neutrals, and caprolactam (nylon monomer). Flow data for the sampling days (mean daily discharge) were collected from the State gaging station located on Hogue Creek at Route 614, downstream of the fire site. The flow data and selected water quality data are summarized in Table 2.

The ERT participated with the State in conducting a water quality survey on November 18, 1983. See Figure 4 for sampling locations.

The surface water study consisted of sampling water and sediment from the affected waterways between the lower containment pond and the gaging station at Route 614. The Microtox® unit was employed as a rapid and sensitive indicator of toxicity associated with the tire fire leachate because the major constituents, aromatics and phenolics, give excellent Microtox responses. However, the Microtox measures toxicity to bioluminescent marine bacteria, which would seem to be of small value in estimating the environmental impact on the Hogue Creek ecosystem. Therefore, selected samples were analyzed chemically to determine whether the Microtox results correlated with the known toxicity of chemical compounds present to human health and indigenous aguatic life. Real time measurements of pH and temperature were made to determine whether large quantities of benzoic acid and/or heat from the leachate could be influencing stream toxicity. ERT chemical samples were also analyzed for total organic carbon (TOC) as a relative indicator of total contamination.

Upstream control samples for complete analysis were taken on the presumably uncontaminated western tributary to the lower containment pond, and on Hogue Creek about 1000 feet upstream of the confluence with Massey Run. Stream flow was estimated at the Hogue Creek control station using a portable velocity meter and a tape measure. Massey Run could not be gaged accurately because it was too shallow and had poor channel characteristics. Its flow was determined by the difference in flow on Hogue Creek above and below the confluence.

Samples for complete analysis were also taken at the mid-point in Massey Run and in Hogue Creek about 1500 feet downstream of the confluence. Streamflow was also estimated at the latter station. Duplicate samples were taken by the WCB for purgeable organic analysis at both of these stations.

Microtox-only samples were taken in the lower containment pond and at three intermediate points along Massey Run (two above and one below WCB Station 01) and at two points downstream on Hogue Creek (near the point where a small fish kill had occurred earlier and at the gaging station).

The following table summarizes the water analyses performed by the EPA (ERT) and the State (WCB) for the samples taken on 11/18/83:

Station # (ERT/WCB)	Purgeable Organics	Acid Compounds	Base/ Neutrals	TOC/Phenols/ Cyanide	Microtox

The State water quality data for these samples are included in Appendix B (report dated December 5, 1983). The ERT chemistry data is summarized in Table 3 (5 pages). The ERT Microtox Data is summarized in Table 4. The full Microtox Report is included as Appendix C.

2.3 GROUNDWATER

The geology of the site suggests subsurface contamination is a possibility. Preliminary investigations have revealed there is considerable artesian pressure in the lower aquifer which may not permit infiltration by the oily leachate. However, the probability of fracture flow or flow along the bedding planes cannot be ruled out without further study. As of this date, the well drilling program is nearing completion as planned, except that unforeseen problems due to weather and equipment failure have interfered with the schedule. Once the wells are in place, the ERT and the WCB will conduct the necessary well testing, sampling, and analysis. The groundwater report will be included as an addendum to this Preliminary Environmental Assessment.

The Groundwater Study Plan is included as Appendix D.

3.0 DATA INTERPRETATION

This chapter addresses the significance of the analytical findings in the areas of emissions, transport, and environmental concentrations. Where statements are made regarding health impacts, they should be considered very preliminary subject to a review to be made by the Centers for Disease Control (CDC).

3.1 AIR

Field monitoring of airborne organic vapors and particulates resulting from the tire fire revealed significantly elevated levels in the nearby environment. Concentrations were sufficient to be considered hazardous in the smoke plume given prolonged exposure and sufficient to cause concern

for potential exposure to gusts of smoke and exposure to plume settlement downwind. Subsequent chemical analysis confirmed the field monitoring results and supported the recommendation of an air pollution alert by ERT and the CDC on November 4, 1983. Subsequent to this recommendation, VA Department of Health released a public health advisory regarding potential plume exposure.

The duration and magnitude of the exposure hazard are principally related to the source strength and its changes with time and the air dispersion and dilution characteristics and their changes with time. As the fire loses its power, the source strength diminishes. Periodic flare-ups produce only a fraction of the original emission rate on a daily basis. If dispersion does not also decrease proportionately, exposure potential decreases dramatically. Restructuring of the exposure scenario mandates reconsideration of acceptable emission concentrations.

The initial approach used by the ERT is to estimate safe air concentrations using a method developed by Monsanto Corporation and modified slightly by EPA. We term the method, "Public Safety Factor" or PSF. The method consists of taking the American Conference of Governmental Industrial Hygienists (ACGIH) Threshold Limit Values (TLV's) for the workplace and adjusting them for a 24-hour, seven-day per week exposure period. To allow for the increased sensitivity of the general public as opposed to workers, for possible synergistic effects and for eliminated recovery (or purge) time, a safety factor of 1/100 is also applied. A small buffer is included to provide an early warning function. In short, acceptable air levels for longterm exposure may be estimated by dividing the ACGIH Time-Weighted Average criteria by 440.

This method is especially valid for gaseous emissions and respirable particulates. For larger particulates and certain skin active substances more latitude is warranted and extremely low permissible concentrations must be viewed cautiously. The particulate data calculated from the RAM studies is a case in point. The TLV for benzene soluble coal tar pitch volatiles or particulate polynuclear aromatic hydrocarbons (read "smoke") is 0.2 mg/m^3. Applying the PSF method, yields an acceptable concentration of about 0.0004 mg/m^3. However, the background levels observed at the control station ranged from 0.01 to 0.06 mg/m^3. In such cases, it is more reliable to consider an incremental increase above background as an action level. In this case, we used a sustained particulate level of 0.1 mg/m^3 as cause for concern.

Except for direct exposure in the plume (Station No. 1), dispersion was generally sufficient to cause at least a tenfold dilution at the nearest downwind station (No. 5) even though the smoke was visibly present. Since the volatile organics of greatest concern, chloroform and benzene, were present at Station No. 1 at maximum concentrations of about 20 and 30 times their respective PSF limits, it is readily apparent that they would quickly diminish to acceptable levels a short distance downwind. Hence, it may be concluded that no widespread environmental problem can exist.

The localized problem is another matter. The volatile organics and soot as measured at the perimeter of the fire (Station No. 1), present levels which range from marginally hazardous to very hazardous in reference to accepted

TLV's. Working in the fire area itself (within the perimeter where there is less dilution) provides exposure opportunities well in excess of acceptable limits. Extreme health and safety measures are required to limit exposure in this area.

3.2 SURFACE WATER

Toxic substances in toxic amounts have migrated from the tire fire site into the Hogue Creek system. Water quality data of the State and EPA indicate emissions have been occurring since the fire began and will continue for an undetermined time into the future. Aside from the first slug of oil which escaped into the system, seepage and leachate into Massey Run and Hogue Creek persisted as of the last sampling date for which the ERT has reported data (i.e., December 19, 1983). The evidence indicates that toxic substances are being carried from the site in shallow groundwater which outcrops into Massey Run and into Hogue Creek via Massey Run and along the alluvial aquifer associated with it.

The available data indicate that ever since the surface flow of oil has been placed under control, pollutant loadings to Hogue Creek have been related to total stream flow, which is reflective of a system where contaminants are dissolved in shallow groundwater closely associated with an outcropping stream system, such as Massey Run. However, the toxic effects of the leachate appear to be confined to Massey Run under the current situation. Although toxic substances are reaching Hogue Creek, they do not appear to warrant extraordinary concern over environmental effects.

The first set of data received were the Microtox results from water and sediments sampled on November 18th. The data for those water samples, which yielded any significant toxicity, are shown graphically in Figures 5 and 6. The minimum dilution of the water samples was 45%, which means a significant toxic response must occur at about a 1:1 dilution before it may be detected by the unit. Moreover, samples which do not yield a toxic response in the test at the highest concentration (minimum dilution) might actually still have a toxic effect at full strength. However, no toxicity would be detected. This is but one of the reasons correlative chemical data is valuable in interpreting the results.

As shown in the figures, toxicity was evidenced in the lower containment pond and in Massey Run as far downstream as Hogue Creek. Below the confluence, toxicity of Hogue Creek water was reduced to non-detectable levels, although significant toxicity was still evidenced in the sediments immediately downstream. Samples from stations further downstream yielded no significant toxicities in either water or sediments.

Table 5 shows a summary of Microtox toxicity testing and selected chemical data for each water station sampled on November 18th. The Microtox results are expressed as percent waste eliciting EC_{50} and EC_{20} responses. An EC_{50} is an "effect concentration" of sample resulting in a 50% light reduction and an

EC_{20} is an "effect concentration" resulting in a 20% light reduction. These numbers are determined by interpolation, where possible, or extrapolation, where necessary, from the curves shown in Figure 5 and 6, using standard bioassay methods.

The summary (Table 5) includes chemical data for the significant contaminants likely to produce an acutely toxic effect on the Microtox organisms. These chemicals include phenol and total phenolics, caprolactam, cyanide (CN), and total organic carbon (TOC). Analysis of this table yields no striking results. While we can state in general that significant Microtox toxicities are associated with high concentrations of phenolics and caprolactam, the data cannot be used to prove cause and effect. If either of these chemical indicators were itself the causative agent, we would have observed more toxicity in the Hogue Creek samples (01830 and 01831) than in the tributary to the lower containment pond (01838). A scan of the raw data also shows no qualitative difference between samples 01838 and 01831. More than likely, the toxic effect is exerted synergistically, with contributory agents which were not quantified.

Evaluation of the chemical data taken by the State and EPA shows considerable time variability over the first month and a half since the fire began (See Table 2). However, a relationship to streamflow is also suggested. One possible relationship may be postulated by making a logical assumption that caprolactam loading on Hogue Creek is related to gaged stream flow. Since only a few real data points are available, no conclusions may be drawn, but the concept is useful for predicting future conditions. If the relationship continues to hold with additional sampling, we could make an estimate of the loading on Hogue Creek for the duration of the incident using State flow records. Using the data in Table 2 for November 29th and December 6th and 19th, a standard curve may be prepared for log-linear regression caprolactam loading (lbs/day) vs. gaged flow (cfs). Using the flow data for other sampling dates, we can calculate estimated loadings for each. The standard curve is shown in Figure 7. Using estimated loadings and measured flows, one may then estimate the caprolactam concentrations at the gaging station. Admittedly, the level of confidence is very low, but a rough indication is still useful.

3.3 GROUNDWATER

Preliminary Microtox data on the groundwater study program indicate that the deep aquifer has not been contaminated downgradient from the fire site. However, Microtox toxicity was evident in the water table aquifer downgradient.

On January 31, 1984, the two completed downgradient wells - TF2D and TF2S, and the partially completed upgradient well - TD1D, were sampled by ERT. ERT samples were to be analyzed for purgeable organics and Microtox toxicity. ERT also collected samples for the State WCB, which is to provide a more complete chemical analysis.

The Microtox data for the ERT samples was reported verbally on February 6, 1984. The deep well TF2D and the half-drilled well TF1D (depth at the time was 54 feet) yielded no detectable toxicity. The downgradient shallow well (TF2S) yielded the results which follow:

Dilution	Normalized Percent Light Decrease
5.65%	8.4%
11.3%	21.8%
22.5%	41.0%
45.0%	38.0%

The resulting curve is plotted in Figure 8. Interpolation yields an EC_{20} of 10.3%, which corresponds to the results of the marginally contaminated sample from the westerly tributary to the lower containment pond. Compare the 12.0% light reduction for sample 01838.

Further discussion must wait until the chemical data is received from the State and EPA.

4.0 CONCLUSIONS AND RECOMMENDATIONS

This chapter draws together the findings to date in the air, water, and groundwater studies to reach general conclusions as to the environmental impact of the present and projected situation at the Rhinehart site. It is not intended to assess environmental damage that may have occurred during the course of the incident.

4.1 CONCLUSIONS

While emission of organic vapors from the fire did reach concentrations significant enough to require the use of personnel protection equipment, they did not reach concentrations which were considered hazardous beyond a short distance downwind of the source. Plume dispersion was adequate to ensure an effective exposure would not occur beyond the Rhinehart property.

Particulate emissions from the fire were severe, achieving levels of at least 40 mg/m^3 in the smoke at breathing height along the perimeter of the fire. This concentration is 200 times the recommended TLV for "smoke" and 400 times the level of concern established by CDC and ERT for particulates. Although good plume dispersion characteristics generally prevailed during the height of the incident, the decisions to provide smoke exposure warnings on and off-site were well justified.

The diminishing source strength of the fire is reducing the perimeter of the area of concern over human health from airborne contaminants but the exposure risk remains in the immediate vicinity of the fire.

Emissions of oil and water mixtures have contaminated the water and sediments of Massey Run. The toxicity effect, as measured by the Microtox, extends at least to the confluence with Hogue Creek. The chemical evidence does not conclusively link the Microtox results with a particular chemical substance. Rather, a combined effect of the materials present is indicated.

Residual contamination persists in Massey Run. It appears that the shallow groundwater table, the sediments, and the stream itself are interrelated and are serving as a reservoir and transport mechanism for contaminants which once flowed from or are leaching from the fire area. The total quantity of material present and its leaching rate cannot be determined at this time, hence the duration of the effect cannot be estimated.

There appears to be a relationship between organic loading (as measured by caprolactam loading) and streamflow in Hogue Creek. This relationship could indicate higher pollutant loading will occur at high streamflows. Spring flows could result in toxicity being manifested in Hogue Creek below the confluence.

The shallow groundwater downgradient from the fire site is contaminated to the extent that a Microtox response is elicited. However, the toxicity would be classified as moderate. Based on limited data, the deeper aquifer appears to be clean. Preliminary flow studies indicate that the shallow aquifer flows towards Massey Run via the Rhinehart Pond drainage system or by subsurface transport. The deep aquifer seems to flow in the same direction and may outcrop closer to Hogue Creek. Conclusions regarding the environmental impact on groundwater must be deferred until the groundwater studies are completed.

Overall, the environmental impact of the tire fire does not appear to be severe at this time. Long term impacts from air releases appear to be negligible. The immediate surface water impact from large releases of oil has passed and the potential for instantaneous large releases has diminished with reduced oil production in the fire. Outcropping of leachate into Massey Run and Hogue Creek is likely to occur for an undetermined time, but it appears that any major toxic effects will be confined to the Run and will not be widespread in Hogue Creek. Quantities of contaminants of non-detectable levels may reach the downstream water supply intakes until acclimated stream bacteria become more active in the warmer weather and biodegradation is enhanced. The groundwater contamination issue remains open at this time.

4.2 RECOMMENDATIONS

Given the current site characteristics, there is no need for additional air monitoring. Should major changes occur in source strength or distribution, another air monitoring program may be needed.

Should mitigative action be taken at the site, an air monitoring program should be established as part of it.

Personnel safety requirements applied during the incident should continue to apply adjacent to the fire area.

Water quality monitoring should be continued on a bi-weekly to monthly basis at the WCB monitoring stations to establish a trend in contaminant loadings. We recommend that the State continue to monitor for caprolactam as well as for purgeable organics since caprolactam appears to be a useful indicator of loading rate.

Streamflow records appear to be an intergral part of determining the magnitude and duration of the environmental impact of the leachate. Hence, obtaining flow records for Hogue Creek and opportunistic flow measurements on both streams should be considered part of the surface water monitoring program.

We recommend the groundwater studies be carried to their conclusion and that the resulting report be appended to this environmental assessment by reference.

memorandum

DATE: January 30, 1984

REPLY TO ATTN OF: Rodney D. Turpin Rodney D. Turpin
Safety and Occupational Health Manager

SUBJECT: ERT Air Monitoring Efforts at the Rhinehart Tire Fire, Winchester, VA

TO: Thomas Massey, Senior On-Scene Coordinator
EPA, Region III

THRU: Joseph P. Lafornara, Chief H. Allen for JPL
Annalytical Support Section

ACTIONS TAKEN

An air sampling program was developed and implemented on November 3, 1983, following all five steps of the ERT Air Monitoring Guides. The ERT air monitoring efforts covered a period from November 3, 1983 to November 30, 1983. In addition to the standard collection media, samples were collected using the ERT 2-Stage Tenax/Chromosorb 102 thermal desorption tube. A total of 74 samples were collected for analysis. Our program consisted of:

A. Modifying NIOSH P&CAM methods 127 and 168, respectfully, to scan for organic vapors and aromatic amines.

B. Following the ERT 2-Stage Tenax/Chromosorb 102 collection tube procedures. Analyses were performed on a GC/MS utilizing thermal desorption extraction methods.

C. Collecting particulate filter cassettes for both organic and inorganic analysis.

D. Surveying the site with portable field instruments. Instruments used for this survey were the photoionization detector (PID), organic vapor analyzer (OVA's) and a Real-Time Aerosol Monitor (RAM-1).

E. Collecting thermal desorption tubes for on-site OVA FID/GC analysis.

F. In addition to monitoring the plume under normal burning conditions, the fire was also monitored during phases of the spraying operation.

G. Off-site grab sampling for particulates using the RAM-1.

OPTIONAL FORM NO. 10
(REV. 1-80)
GSA FPMR (41 CFR) 101-11.6
5010-114

☆ U.S. GOVERNMENT PRINTING OFFICE: 1983 O - 381-526 (7290)

The sampling scheme consisted of one background station, two off-site downwind stations, 6 on-site stations, and several off-site grab samples with the RAM-1. The following is a breakdown of the type of samples:

1. NIOSH P&CAM - 168 (Aromatic Amines) 3-stage silica gel tubes: 11 samples.

2. NIOSH P&CAM - 127 (Organic Vapor Scan) 150 mg carbon tubes: 5 samples; 600 mg carbon tubes: 15 samples.

3. ERT 2-stage tubes (Organic Vapors) Tenax/Chromosorb 102 collection tubes: 23 samples.

4. OVA FID/GC thermal desorption collection tubes: 6 samples.

5. Particulate cassette analyzer for organic/inorganic contaminants: 14 samples.

RESULTS

See Attachment No. 1 for a summary sheet of sample numbers, volumes, and stations. Attachment No. 2 locates the sample stations. The following is a summary of the results of the actions taken:

A. The following are highlights of the P&CAM 168 aromatic amines samples (See Attachment No. 3 for data summary and detection limits):

1. Sample No. 882/38 collected from Station No. 1 on 11/04/83 was found to have an unknown peak. A gas chromatograph/mass spectrometer (GC/MS) analysis identified it as 0.03 ppm Naphthalene.

2. Sample No. 868/9 (Station No. 1, 11/22/83) and 886/16 (Station No. 1, 11/22/83) were found to contain 0.044 ppm and 0.067 ppm of Aniline, respectively.

3. Sample No. 868/9 (Station No. 1, 11/22/83) and 886/16 were found to contain 0.0092 ppm and 0.014 ppm of p-Nitroaniline.

4. Sample No. 868/9 (Station No. 1, 11/22/83) and 886/16 were found to contain 0.007 ppm and 0.018 ppm of p-Ansidine.

B. The following are highlights of the particulate, mixed cellulose ester filter (MCEF) cassette samples. Some filters were digested with Nitric Acid and particulates were dissolved in the same acid. The resulting solution was diluted to a 50 milliliter volume with 5% HNO_3 in distilled water and analyzed by atomic absorption for inorganic contents. Other filters were extracted with Carbon Disulfide and the resulting extracts were injected in gas chromotographs to evaluate organic content. See Attachment No. 4 for data summary and detection limits.

1. The 7 particulate samples collected for organic analysis did not identify any concentration above the GC detection limit.

2. Sample No. 889/15 (Station No. 1, 11/22/83) identified 0.001 mg/m^3 Arsenic, 1.532 mg/m^3 Zinc, and 0.006 mg/m^3 Copper.

3. Sample No. 861/18 (Station 6, 11/22/83) identified 0.007 mg/m^3 Zinc.

4. Sample No. 865/21 (Station 3, 11/22/83), background identified 0.054 mg/m^3 Zinc.

5. Sample No. 888/36 (Station No. 5, 11/04/83) identified 0.003 ug/l of Zinc; 0.051 ug/l Tellurium and 0.021 ug/l of Arsenic.

C. The following are the highlights P&CAM 127 method organic vapor analysis (See Attachment No. 5 for data summary and detection limits):

CHEMICAL	SAMPLE No./DATE	STATION	CONCENTRATION (ppm)

D. The following are highlights of the ERT 2-stage Tenax/Chromosorb 102 data (See Attachment No. 6 for data summary and detection limits). Those collected on 11/03/83 revealed the following low levels:

1. Background samples: - The 11/04/83 background samples did not identify any significant compounds after correction for the blank.

Benzene	<0.02
Possible Hydrocarbon	<0.03
Unknown	<0.03
Hydrocarbon	<0.03

The 11/22/83 background samples revealed the following compounds:

Nonanal	0.002
Decanal	<0.002
Possible Lauric Acid	0.002
Myristic Acid	0.002
Possible Palmitic Acid	<0.0009
Benzaldehyde	0.006
$E_{10}H_{14}$ Alkylbenzene	<0.004
Styrene	<0.005
Acetophene	<0.004
Ethylstyrene	<0.004
Unsaturated Hydrocarbon	<0.003
Hydrocarbon and Unknown	<0.002
Unknown	0.007
Unknown	0.01
Unknown	0.04
Acetic Acid	0.016

2. While the number of compounds identified is too large to summarize, the concentrations ranged from <0.001 ppm for Ethylbenzene, Xylene, Styrene (Sample No. A21, 11/04/83) to 1 ppm for Benzene (Sample No. K/18, 11/04/83 and Sample No. F/13, 11/22/83) and Toluene (Sample No. F/13, 11/22/83).

3. Station No. 1 samples were consistently positive while the other samples did not identify any significant concentrations with the following exceptions:

   a. Station No. 4, sample R/20, 11/04/83 identified 18 compounds ranging in concentration from 0.004 ppm for Trimethyl phenyl indane to 0.26 ppm for Benzene.

b. Station No. 5, sample A/21, 11/04/83 identified 9 compounds ranging in concentrations from <0.0009 ppm for Naphthalene to 0.006 ppm for Toluene.

c. Station No. 5, sample I/25, 11/04/83 identified 5 compounds ranging in concentrations from <0.2 ppm for Trichlorofluoromethane, Ethylbenzene and Xylene to 0.4 ppm for Benzene.

d. Station No. 6 (Decon), sample J/12, 11/22/83 identified 9 compounds ranging in concentrations from 0.004 ppm for an Unknown to 0.01 ppm for an Unknown and Acetic Acid.

E. Attachment No. 7 is the result of the organic vapor analysis (FID/GC) from the thermal desorption collection tubes on-site. The following is a summary of this data:

1. Station No. 1 results revealed 12 GC peaks for 11/03/83 and 10 GC peaks for 11/04/83.

2. Station No. 4 results revealed 2 GC peaks for 11/03/83 and 4 GC peaks for 11/04/83.

3. Station No. 3 (background) results revealed 1 GC peak for 11/03/83 while Station No. 5 results revealed 5 GC peaks for 11/04/83.

F. On-Site grab samples with the Real-Time Aerosil Monitor (RAM-1) revealed the following:

1.	11/03/83 - Station No. 1	(a.m.)	22.0	mg/m^3	
	- Rhinehart House	(a.m.)	0.03	mg/m^3	
2.	11/04/83 - Station No. 1	(a.m.)	34.6	mg/m^3	
	- Station No. 5	(a.m.)	19.0	mg/m^3	
3.	11/22/83 - Station No. 1	(2 p.m.)	40	mg/m^3	
	- Station No. 3	(2 p.m.)	0.010	mg/m^3	(Background)
	- Station No. 4	(2 p.m.)	0.038	mg/m^3	
	- Station No. 5	(2 p.m.)	1.40	mg/m^3	
	- Station No. 6	(2 p.m.)	0.014	mg/m^3	
	- Station No. 7	(2 p.m.)	0.014	mg/m^3	
4.	11/22/83 - Station No. 3	(10 p.m.)	0.060	mg/m^3	(Background)
	- Station No. 4	(10 p.m.)	0.06	mg/m^3	
	- Station No. 5	(10 p.m.)	0.06	mg/m^3	
	- Station No. 7	(10 p.m.)	0.045	mg/m^3	

5. 11/23/83 - Station No. 3 (2 a.m.) 0.015 mg/m^3 (Backgr
- Station No. 4 (2 a.m.) 0.024 mg/m^3
- Station No. 5 (2 a.m.) 0.026 mg/m^3
- Station No. 7 (2 a.m.) 0.026 mg/m^3

6. 11/23/83 - Station No. 3 (6:30 a.m.) 0.050 mg/m^3 (Background)
- Station No. 4 (6:30 a.m.) 0.028 mg/m^3
- Station No. 5 (6:30 a.m.) 0.090 mg/m^3
- Station No. 6 (6:30 a.m.) 0.040 mg/m^3
- Station No. 7 (6:30 a.m.) 0.130 mg/m^3

G. Off-Site grab samples with the RAM-1 revealed the following:

1. On 11/03/83 Rt. 608 downwind of sites ranged from 0.04 mg/m^3 to 0.07 mg/m^3 with the exception of a grab sample collected at the Raymond A. Carter residence which was 0.233 mg/m^3.

2. 11/30/83 - Station No. 1 Off: - 0.19 mg/m^3
- Station No. 2 Off: - 0.20 mg/m^3

CONCLUSIONS

An important factor to consider in reviewing this data is that the ERT air monitoring guides are designed to give a broad spectrum of possible air contaminants. While the type of collection media, flow rates, humidity, ambient temperatures, etc. all have some effect on the reported concentrations, it is correct to say that the amounts reported are the minimum amounts present during the sampling period. This is especially true with the ERT 2-stage Tenax/Chromosorb 102 tube. This tube has only been used at a few sites and we are still experimenting with the sample rates and volumes.

While the concentrations reported by the ERT 2-stage tube are relatively low when compared to the NIOSH P&CAM samples collected at the same stations, the number of compounds identified is considerably greater. This indicates there are possibly some unidentified concentrations of compounds present that are not collected/desorbed from the P&CAM methods or their concentrations are below the P&CAM detection limits.

On 11/03/83 and 11/04/83, ERT recommended to the on-scene coordinator and CDC that an Air Pollution Alert be released advising those with respiratory problems to keep all windows closed and avoid being outside under the plume. This recommendation was based on the data furnished by the field instruments (Real-Time Aerosol Monitor, RAM-1, and Organic Vapor Analyzer, OVA (FID/GC) as well as on-site observations of plume behavior. All off-site data generated by the various collection media and techniques were immediately reported (verbal) to the EPA Region III, TAT, at the command post. Either Region III, TAT, or ERT relayed this information to CDC. ERT was in agreement with the CDC Air Pollution Alert notice.

The conclusions are based on the data collected during the sampling period and potential contamination. If site conditions differ from the sampling period, additional sampling is recommended.

When applicable, we use an estimated health alert concentration, which we term the "Public Safety Factor" (PSF) to assist in the evaluation of the air data. While the Public Safety Factor is not a safe/non-safe designation for a specific concentration, it is an action level used by ERT during chemical spill, fires, explosion responses, etc. to alert those professionals whose responsibility it is to make occupational health and safety, as well as public health/ environmental effects decisions from air data. The Public Safety Factor is the American Conference of Governmental Industrial Hygienist TLV's expanded to include a 24 hour exposure condition while providing a safety factor. PSF is calculated by dividing the TLV by 440.

A. P&CAM 168 AROMATIC AMINES:

1. Of the two days (11/04/83 and 11/22/83) samples were collected and analyzed for aromatic amines only the 11/22/83 sample results indicated a positive finding. None of the samples indicated a level at or near the TLV and/or PEL (OSHA's Permissible Exposure Level). Three of the four positive samples did exceed the Public Safety Factor; however, the positive results were found only in the plume.

   Three of the aromatic amines Public Safety Factors are based on TLV's with a skin notation. In evaluating the extent of potential hazard, one must consider potential route(s) of exposure. The data indicated that the aromatic amines were collected only at Station No. 1, which was directly inside the plume, and only on 11/22/83. Since the most logical route of exposure is direct contact with the plume, and since a 100-fold dilution is normally achieved a short distance away, it was concluded that the aromatic amines present did not present a grave health risk to the surrounding public or the environment. However, if site conditions vary significantly from the period sampled further evaluation is recommended. In addition, the fact that aromatic amines are present should be evaluated as a potential for exposure from the Occupational Health and Safety prospective.

B. ORGANIC/INORGANIC PARTICULATES:

1. Organics - Since standard sampling/analysis procedures are not published for organic particulates, the sampling method was adapted by modifing P&CAM 127 collecton and extraction techniques. Of the 7 particulate samples which were collected for organic analysis, two were collected within the plume (Station No. 1) and 2 were collected off-site. None of the samples revealed organics above the GC detection limit. Thus, it is reasonable to conclude

that the plume particulates did not contain high concentrations of organics. The data indicates that particulate fall-out should not have an adverse environmental effect.

2. Inorganics - The inorganic pariculate samples revealed the presence of some inorganics at Station No. 1, 6, 3, and 5. The concentrations found at these sampling points were well below the TLV or PEL, and should not pose environmental problems.

C. P&CAM 127 ORGANIC VAPORS:

1. With the exceptions of Stations No. 4 and 5 on 11/04/83, Stations No. 5 and 7 on 11/30/83, and Station No. 1 on 11/04, 11/22, and 11/30/83, the other stations did not detect organic vapors above the GC detection limit. If a peak had been observed other than one of the standards identified in P&CAM 127 and was of sufficient concentration, it would have been analyzed by GC/MS. However, if the peak concentration was not sufficient for GC/MS analyses, the total number of unknown peaks would be added and a total hydrocarbon concentration quantified as if it was Toluene.

2. Of the 14 organic identified by this method, 2 do not have TLV information available (mineral spirits and total hydrocarbons measured as Toluene). Of the 12 organic identified with TLV's 4 compounds did not exceed the Public Safety Factor (Acetone, 1,1,1-Trichloroethane, Methyl Ethyl Ketone, Styrene) while the remaining 8 compounds (See Results section, paragraph (c)(2)) exceeded the Public Safety Factor during at least one sampling period.

   With the exception of Station No. 5 on 11/04/83 (Chloroform 0.08 ppm), and Station No. 4 on 11/04/83 (Chloroform 0.08 ppm), all the other concentrations which exceeded the Public Safety Factor were found at Station No. 1 (plume sample) during the sampling period.

   Since the data showed that the worst-case condition occurs only in the plume and that concentrations exceed the Public Safety Factor action levels by factors generally less than tenfold, it is reasonable to conclude that downwind dilution would mitigate any adverse effects within a short distance. Although the 11/04/83 data was not available when ERT recommended an air pollution alert based on the RAM-1, field FID/GC, and observation, some data was available on 11/09/83 and this confirmed our field readings.

D. ERT 2-STAGE TENAX/CHROMOSORB 102 DATA:

While the ERT 2-stage Tenax/Chromosorb 102 collection tube is still undergoing field evaluation, its objective is to furnish a

convenient screening medium for air samples where multiple contaminants might be present. Also, it provides a rapid analytical turn around time. Since compounds are collected in both stages of the collection tube, it is not possible to determine the amount of break-through. Therefore, the data reported is the minimum concentration of the contaminant.

Of the 14 organics identified by the P&CAM 127 method, the ERT 2-stage collection tube identified 5 of those compounds. While the concentrations are not in total agreement, the following shows their relationship:

COMPOUND	DATE/STATION NO.	ERT 2-STAGE (ppm)	P&CAM 127 (ppm)
Methylene Chloride	11/04/83 No. 1	----	0.24
	11/04/83 4	0.08	----

AR100279

This information was not available when ERT recommended that the CDC declare an Air Pollution Alert based on the field direct reading instruments and visual observations (see below). The The ERT 2-stage tube data confirmed this action after the fact.

E. ON-SITE THERMAL DESORPTION AND FIELD OVA GC/FID RESULTS:

The data collected with this field instrument on 11/03/83 and 11/04/83, indicated the presence of airborne contaminants above background levels at Stations No. 1, 4 and 5. Based on this data as well as the RAM-1 data, ERT recommended an Air Pollution Alert. As additional data were received from the other methods/ collection media, it confirmed the presence of organic concentrations above background at Stations No. 1, 4 and 5.

F. ON-SITE GRAB SAMPLES WITH THE RAM-1:

While the data collected along Route 608 was subject to interference from residential woodburning stoves, the presence of the plume over this area was visually confirmed via a helicopter flight. In addition to the RAM-1 reading varying from 22 mg/m^3 to 40 mg/m^3, visual contact could not be maintained with members of the Air Sampling Team at Station No. 1 some 50-60 feet away.

November 30, 1983

Mr. Kenneth Sullivan
Operations Manager
I. T. CORPORATION - EERU
GSA Raritan Depot
Bldg. 209, Bay F
Edison, New Jersey 08837

CEC Job No. 8695-47
Re: Winchester, VA. Site

Dear Mr. Sullivan:

The samples which you submitted to us on November 7, 1983 were analyzed and reported to you on November 10, 14 and 18, 1983.

One silica gel sample (#882/38) showed presence of an unknown peak which was analyzed by Gas Chromatography/Mass Spectrometer for identification, has been completed. The unknown peak is identified as Napthalene in the range of 20 to 30 micrograms level.

Lab I.D.#	Sample Description	Vol. in Liters	Conc. of Naphthalene (ug)	(mg/m^3)	(ppm)
16275	882/38 Silica Gel 3-Stage	163.6	20-30	0.18	0.03

Above reported results of milligrams per cubic meter and parts per million are calculated utilizing 30 micrograms value. Therefore, this should be considered as maximum exposure.

If there are any questions, please advise. Thank you.

Very truly yours,

Kirit H. Vora, Manager
New Jersey Office and Laboratory

November 16, 1983

Mr. Phil Staats
IT CORPORATION
GSA Raritan Center
Building 209; Bay F
Edison NJ 08837

CEC Job No. 8695-47

Dear Mr. Staats:

The samples which you submitted to us on November 7, 1983, have been analyzed by gas chromatography/mass spectrometry (GC/MS) as requested. I have enclosed copies of the total ion current chromatograms (TIC) and mass spectra for the compounds identified.

Quantitation was performed using an external mixture of chloroform, toluene, 1,2,3-trimethylbenzene, and dodecane. This mixture gives a good combination of retention times and response factors for external standard quantification.

The results have been blank corrected to eliminate compounds not actually present in the field samples.

It is a pleasure to be of assistance to you. Please contact us if you have any questions concerning this report.

Sincerely,

Robert Lieckfield Jr., C.I.H.
Manager, Laboratory Services

MEMORANDUM

TO: Rodney Turpin, ERT

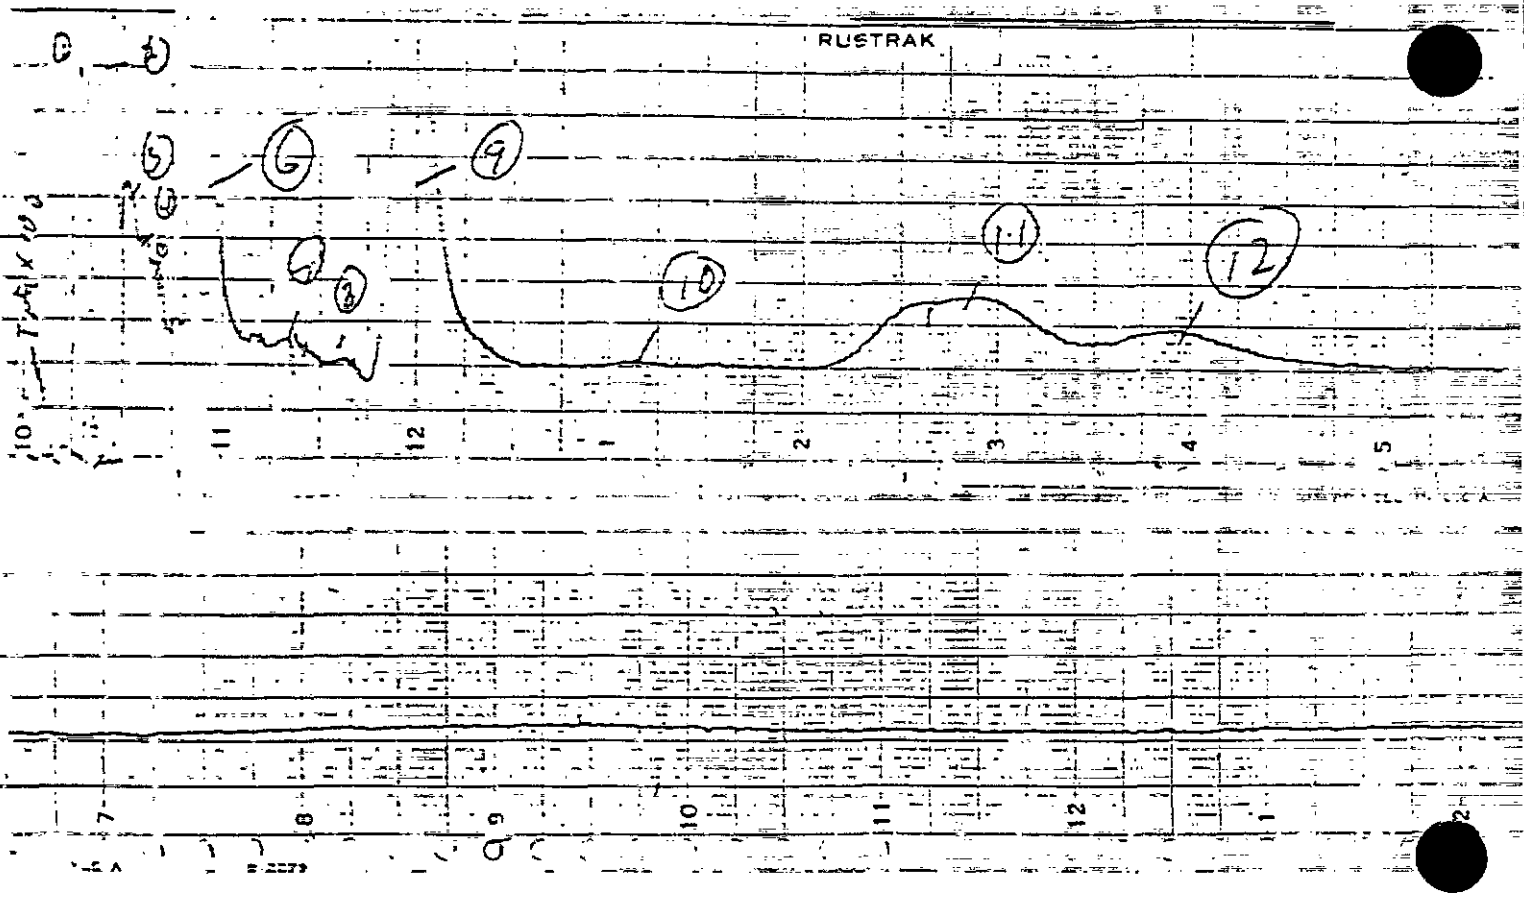
FROM: Philip R. Campagna, ERT/TAT

SUBJECT: Air Sampling and Monitoring At Rhinehart Tire Fire in Winchester, VA. (TDD# 12-8311-02)

DATE: November 29, 1983

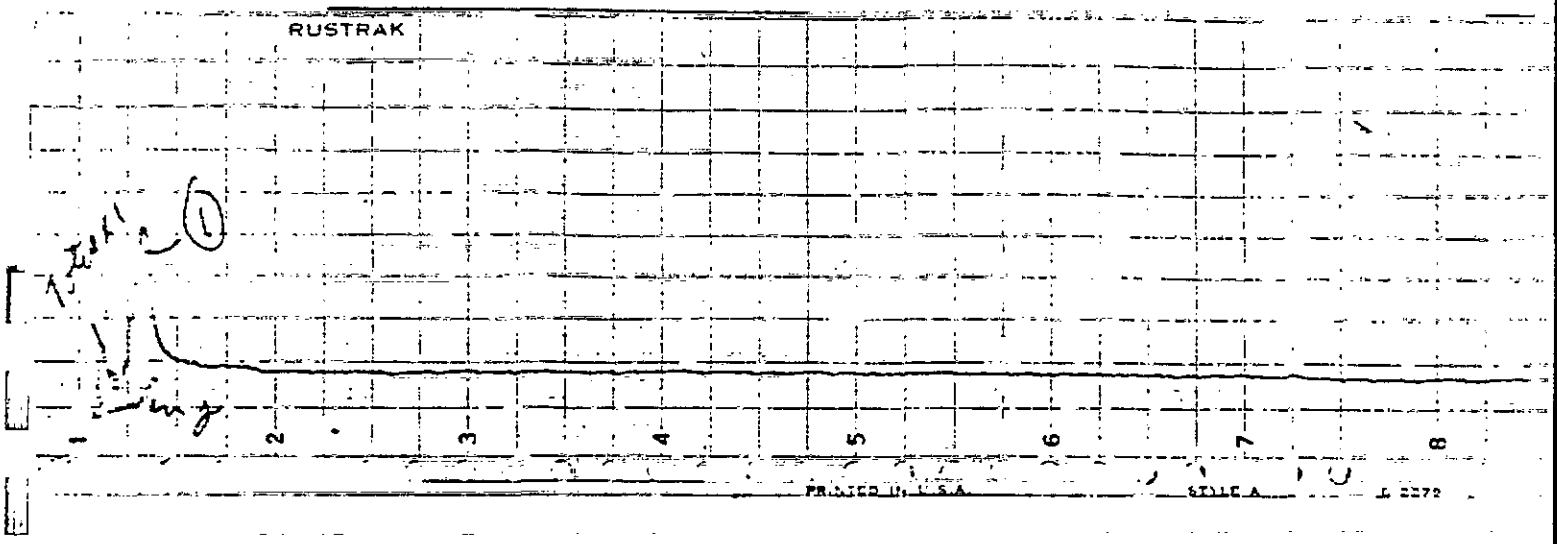
11/08/83

897/14 Station #1. Volume of air sampled (0.55 l/min for 117 min) = 64. 35 l. TWA methane = (120)(0.3)/(64.35) = 0.56 pm. GC: 12 peaks observed Rt. = 0.1, 0.3, 0.6, (0.95 1.4, 2.7, 3.4, 4.2, 7.2 11.4 and 14.3 cms.

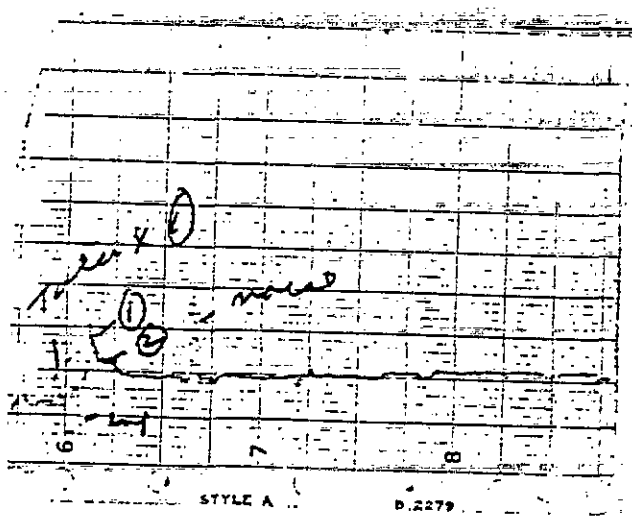


ORIGINAL
(Red)

894/15 Station #3 (Background). Volume of air sampled (0.5 l/min for 160 min) = 83
TWA as methane = (1.0)(0.3)/(83) = 0.003 pm. GC one peaked observed Rt = 0.3 cms.

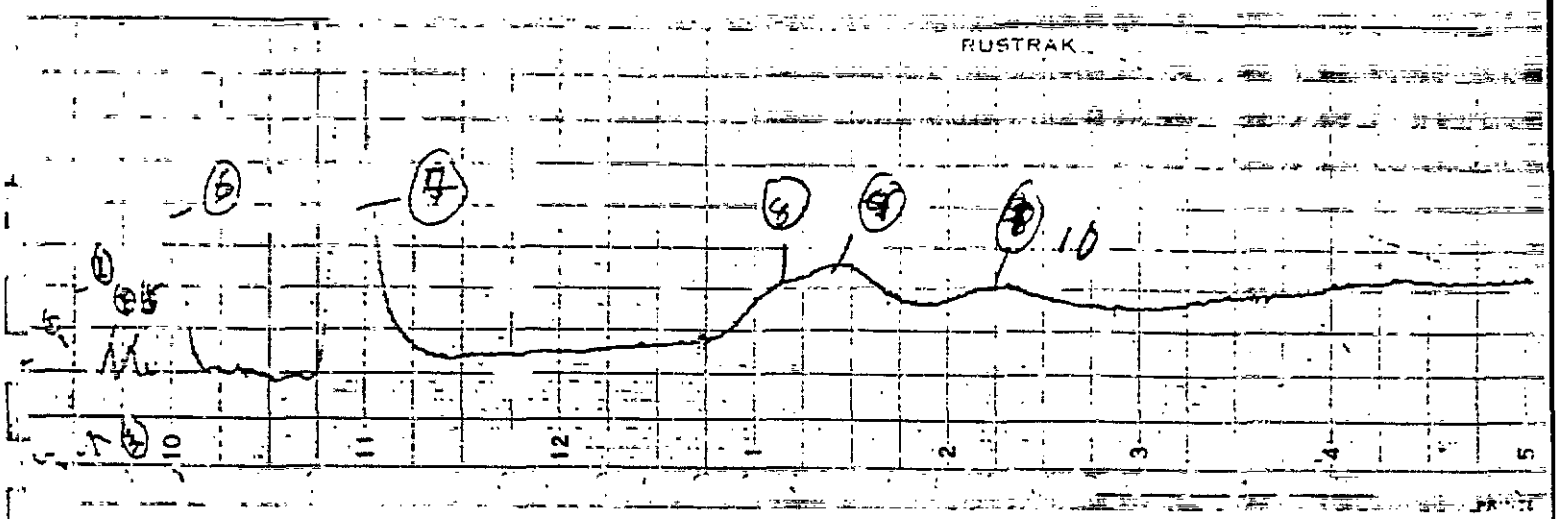


865/16 Station #4. Volume of air sampled (0.5 l/min for 135.4 min) = 67.7 l. TWA
methane = (0.7)(0.3)/67.7) = 0.003 ppm. GC 2 peaks observed Rt = 0.1 and 0.3 cms.

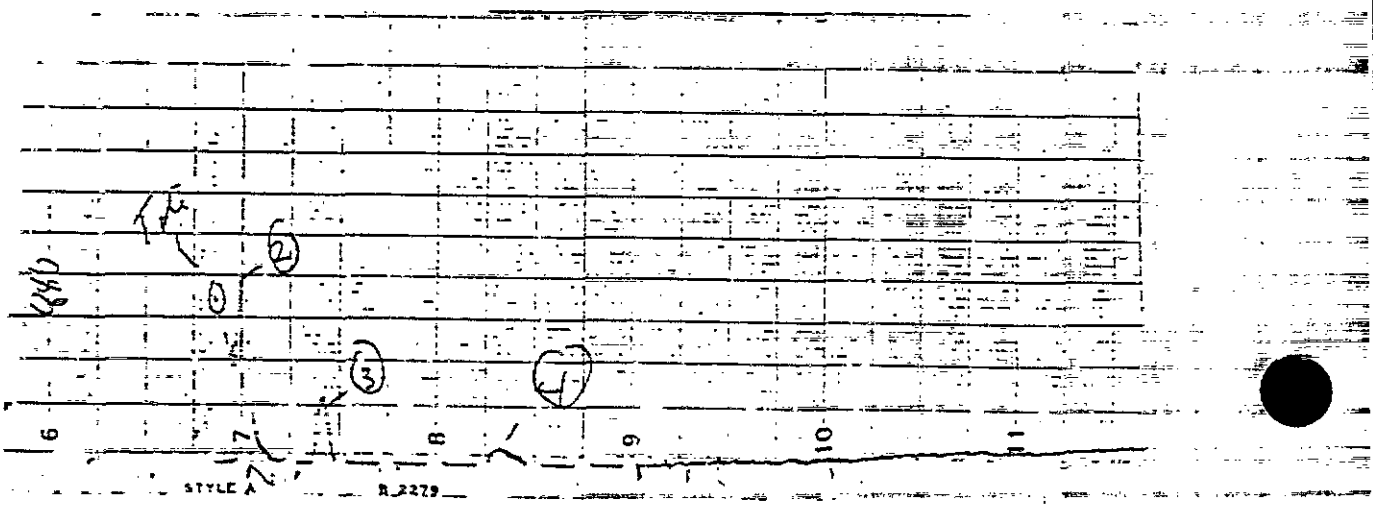


11/04/83

866/42 Station #1. Volume of air sampled (54.4 min at 0.4 l/min) = 22.96 l. TWA methane (70)(0.3)/(22.96) = 0.914 ppm. GC 10 peaks observed Rt = 0.05, 0.1, 0.3, 0 0.85, 1.3, 3.7, 9.5, 10.0 and 12.1 cms.



886/41 Station #4. Volume of air sampled (180 min at 0.4 l/min) = 72 l. TWA as methane = (4.8)(0.3)/(72) = 0.02 ppm. GC 4 peaks observed Rt = 0.1, 0.3, 1.2, and cms.



865/43 Station #5. Volume of air sampled (180 min at 0.5 l/min) = 90 l. TWA as methane = (10)(0.3)/(90) = 0.033 ppm. GC 5 peaks observed Rt = 0.1, 0.2, 0.3, 1.2, 3.1 cms.

ORIGINAL
(Red)

The sediment samples were also all in the pH range of 6.0 to 7.0. The 2:1 dilution scheme compounded by the 5:1 extraction scheme resulted in the following test sample concentrations; 1.2%, 2.3%, 4.5%, and 9.0%. Samples were also rated under the same guidelines established in the aqueous samples. It should be noted that not every aqueous sample had a corresponding sediment sample.

Sample	Rating	Response
1832	Clean	Responses up to 11.3%
1837	Clean	Responses up to 10.2%
1836	Clean	Responses up to 11.6%
1830	Moderate	Responses up to 16.1%
1833	Moderate	Responses up to 17.7%
1831	Moderate	Responses up to 20.3%
1835	Significant	Responses up to 32.0%
1834	Significant	Responses up to 70.8%

Comparison of the sediment and soil samples displayed some signficant trends. Both sediment and aqueous samples 1834 and 1835 displayed, respectively, the highest and second highest microtox NPLD responses. Aqueous sample 1833 displayed a signficant Microtox response with the corresponding 1833 sediment sample displaying a decreased moderate response; owing to a greater dilution test scheme in the sediment sample. This similar trend was also evident in sample 1832 which displayed a moderate respo for the aqueous sample and a clean response for the sediment sample. Samples 1836 , 1837 displayed clean responses in both sample categories. Sample 1831 gave somewha inconsistent results in that the aqueous sample displayed a clean response while th corresponding sediment sample displayed a moderate response. It may be possible th the higher response of the sediment sample might be owing to the extraction/washing any contaminants from the granular sediment sample.

PROJECT SCHEDULE
FOR: Rhinehart Tire Fire
Winchester Virginia

ORIGINAL (Red)

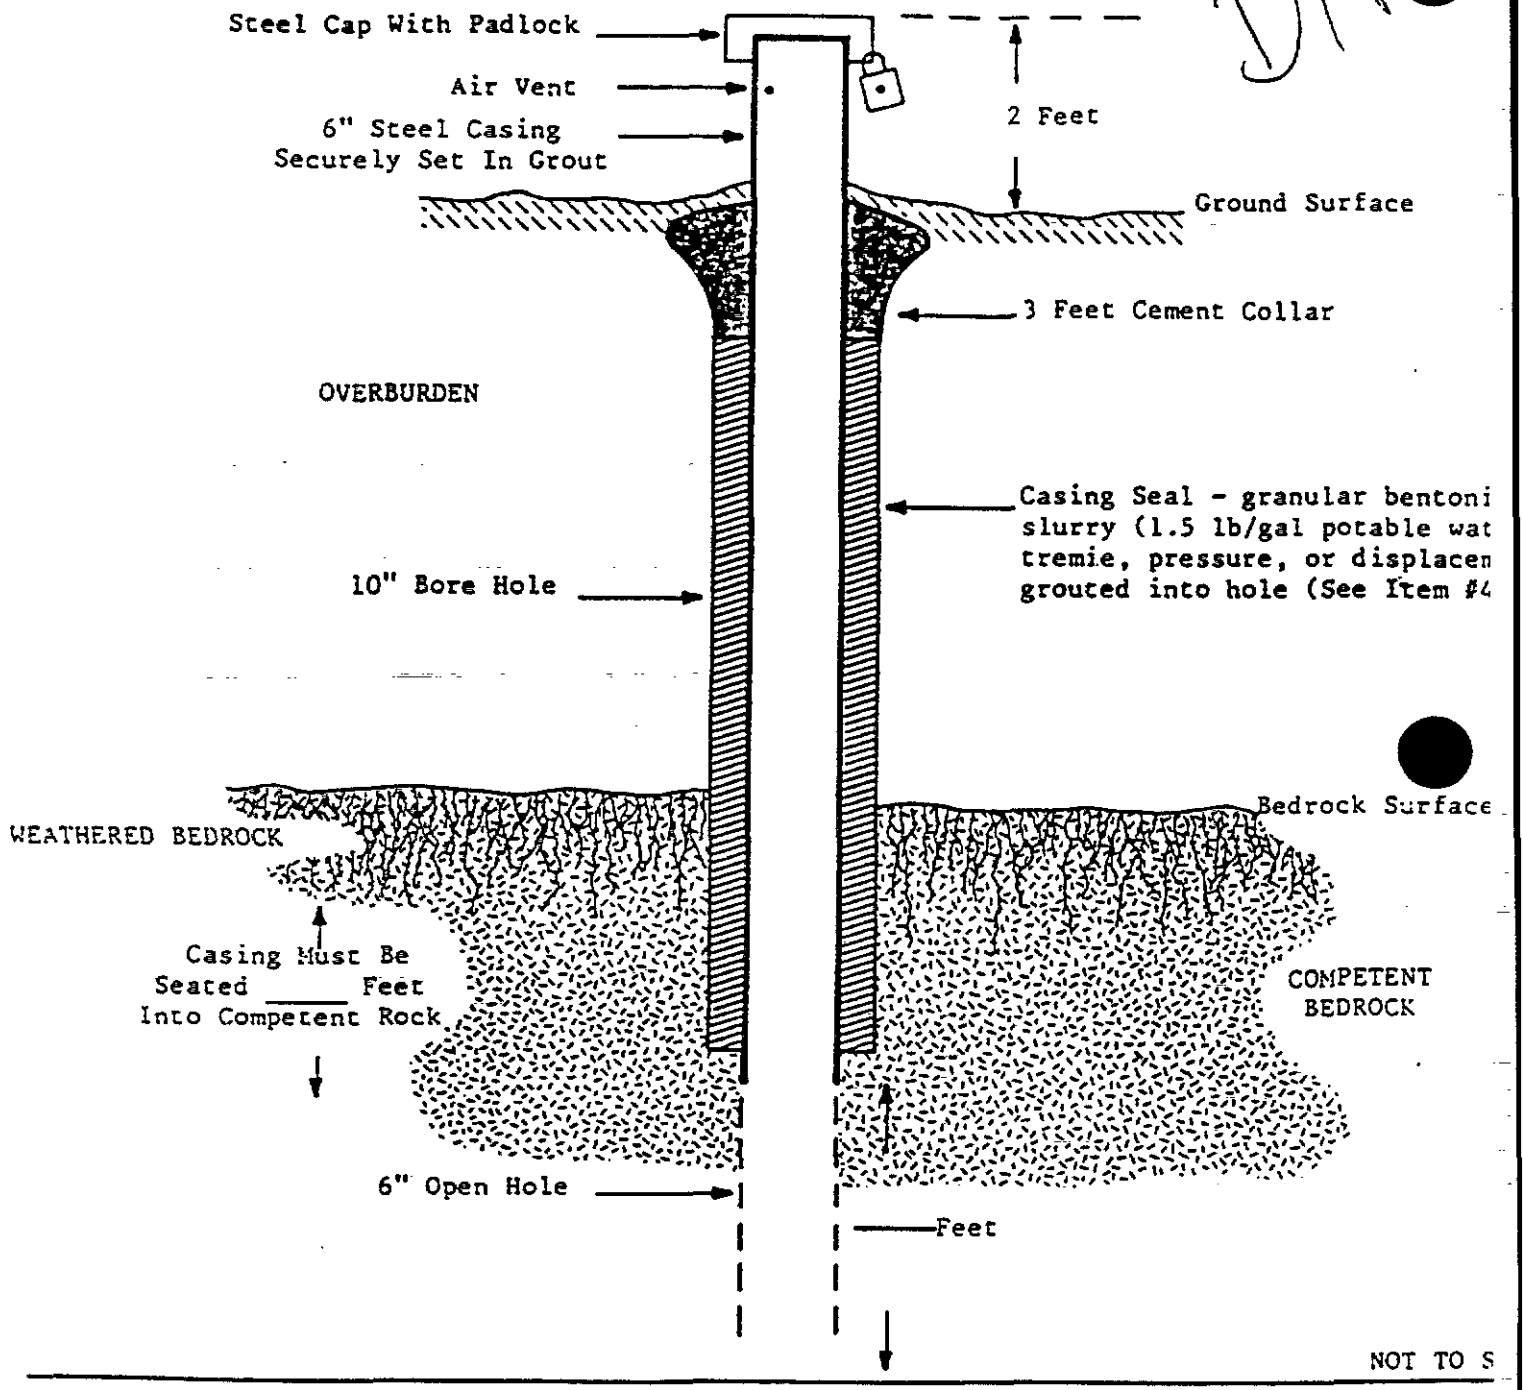
ORIGINAL
(Red)

DRAFT

Site Name: _____

Location: _____

Date: _____



REQUIREMENTS:

1. The contractor is responsible for obtaining all permits or licenses required by state or local governing authorities.

AR100378

ORIGIN
(Red)

2. Oversize borehole, minimum four (4) inches greater than casing diameter drilled through overburden and casing sealed ten (10) feet into competent rock unles shown otherwise above.

3. Approved high grade sodium base, well sealant type, granular bentonite must be used to seal casing. Casing sealant and drilling fluids must be mixed with potable water.

4. Well must be developed upon completion for a minimum of one (1) hour or to yield a turbid-free discharge.

5. The driller must maintain an accurate written log of all materials encountered in each hole, record all construction details for each well, and record the depth of major water bearing fracture zones. This information must be submitted to the IT project manager within one week of the job completion.

6. Cement collar must be installed a minimum of one (1) hour after casing seal has been emplaced.

7. Locking caps must be provided to secure each well.

ADDITIONAL REQUIREMENTS (IF CHECKED):

/ / 1. Split Spoon Samples (In Overburden)_____

/ / 2. Rock Core Samples_____

/ / 3. Dedicated Bailer (Sampler) in Well(s)_____

/ / 4. Borehole Geophysical Log(s)_____

/ / 5. Other_____

_____

* MODIFICATION OF THIS SPECIFICATION MUST BE APPROVED BY THE IT PROJECT MANAGER PRIOR TO IMPLEMENTATION.

Region III
6th and Walnut Streets
Philadelphia, Pennsylvania 19106

Dear Mr. Ostrauskos:

Attached are copies of lab data on water samples taken at the Tire Fire site in Frederick County. The data was performed by the State. Lab. Please note that the date which the lab received the samples is the next day following the sampling.

These are all of the data which I have. As more is received, a copy will be forwarded.

Very truly yours,

R. F. Tesh

Identification No.:

Lab #: 10583-10587

11/3/93
Q=2.

Submitted By: Dave Chance

Analyst: James C. Peterson, Ph.D

Description:
10583--Unnamed tributary to Hogue Creek
Upper portion unnamed tributary--pool of collected product
10584--Unnamed tributary to Hogue Creek
Free flowing stream upper portion, just above big pool of product ✓
10585--X-tributary Hogue Creek
Lower portion unnamed tributary from fire site
10586--Hogue Creek Control
Hogue Creek just above confluence with unnamed tributary from fire site
10587--Hogue Creek
Hogue Creek downstream from confluence with unnamed tributary from fire site

Results:

Priority Pollutants	10584	10585	10586 - Probably Leachate	10587
Benzene	0.9ug/L	1.3ug/L	0.3ug/L	0.5ug/L
Toluene	1.7ug/L	2.3ug/L	<0.2ug/L	<0.2ug/L
Ethylbenzene	4.6ug/L	1.2ug/L	0.8ug/L	<0.2ug/L
Xylenes	2.4ug/L	0.6ug/L	<0.2ug/L	<0.2ug/L
Naphthalene	30 ug/L	10 ug/L	<1 ug/L	<1 ug/L
Fluorene	13 ug/L	4.6ug/L	<1 ug/L	<1 ug/L
Phenanthrene	4.1ug/L	2.0ug/L	<1 ug/L	<1 ug/L
Caprolactam	13 mg/L	4.8mg/L	140 ug/L	210 ug/L

Other Components Identified in 10584, 10585, 10586, 10587:
Benzonitrile, Acetophenone, Tolunitrile, Phthalonitrile, Benzothiazole, Methyl benzothiazole, 1-methyl naphthalene, C_3 benzenes, C_4 benzenes

Sample 10583 was redundant with 10584 and was not analyzed.

MICROTOX ANALYSIS REPORT ON THE SEDIMENT AND AQUEOUS SAMPLES FROM THE RHINEHART TIRE FIRE

On November 18, 1983, eleven aqueous samples and eight sediment samples were taken f Microtox analysis. The samples were taken from the site of the Rhinehart tire fire response in West Virginia. The site was located in a valley in which an estimated f million tires were stored and it was suspected that arson was responsbile for starti the blaze. The Microtox samples taken were from the nearby stream into which some c the contaminants of the fire were flowing.

The samples were received on November 19, and had been kept cool during transport ir ice chest. The Microtox sediment samples were extracted using the method described the microtox application notes M105, September 1, 1982. The recommended extraction procedure required mixing one part sediment samples to five parts distilled water (w/v). Approximately five grams of each sediment sample was added to twenty five milliters of distilled water and placed in a fifty milliter Wheaton bottle. A magne stir bar was added, the bottles were closed with teflon seals and extracted for twer four hours. Samples were allowed to settle and were then filtered using a 0.45um disposable teflon filter. Light readings were taken at five and ten minute interval Operating conditions were as follows Turret assembly 15.0 C, and incubator 2.5 C. I calculations were based upon the mean of duplicate I_5 sample analyses.

DISCUSSION OF RESULTS

ORIGINAL
(Red)

Microtox samples were divided into two categories; sediment and aqeuous sample[illegible]. The aqueous samples were analyzed at a 2:1 dilution scheme resulting in the following sample concentrations: 5.65%, 11.3%, 22.5%, 45.0%. All samples were in the pH range of 6.0 to 7.0. Samples that displayed Microtox NPLD responses between +15.0% and 15 were rated as background clean, those with responses between 15.1% and 30% were rate as moderate, and those with responses above 30.1% were rated as significant. Since actual sampling locations were not provided, the samples were only examined in rela to their relative toxicity to one another. An overall view of sampling locations i relation to the source of contamination as well as controls would significantly aid evaluating the data.

The following data is the catagorizing of the aqueous data in terms of increasing toxicity.

Sample	Rating	Response
Blank	Clean	Stimulatory responses up to +1.5%
1830	Clean	Stimulatory responses up to +8.3%
1831	Clean	Responses up to 1.5%
1836	Clean	Stimulatory responses up to +8.0%
1837	Clean	Responses up to 5.4%
1838	Moderate	Responses ranging from 1.7% to 34.5%
1832	Moderate	Responses ranging from 10.9% to 46.8%
1839	Significant	Responses ranging from 22.2% to 63.2%
1833*	Significant	Responses ranging from 26.0% to 68.0%
1835*	Significant	Responses ranging from 22.0% to 69.0%
1834	Significant	Responses ranging from 26.3% to 75.5%

*These samples appear to share a similar concentration to response range and thus sh the same order of toxicity.
